

Course information 2019–20 EC3120 Mathematical economics

Mathematical modelling is particularly helpful in analysing a number of aspects of economic theory. The course content includes a study of several mathematical models used in economics. Considerable emphasis is placed on the economic motivation and interpretation of the models discussed.

Prerequisite

If taken as part of a BSc degree, courses which must be passed before this course may be attempted:

EC2066 Microeconomics and either MT105a Mathematics 1 and MT105b Mathematics 2 or MT1174 Calculus

Aims and objectives

The course is specifically designed to:

- demonstrate to the student the importance of the use of mathematical techniques in theoretical economics
- enable the student to develop skills in mathematical modelling

Assessment

This course is assessed by a three-hour unseen written examination.

Learning outcomes

At the end of this course and having completed the essential reading and activities students should be able to:

- □ use and explain the underlying principles, terminology, methods, techniques and conventions used in the subject
- solve economic problems using the mathematical methods described in the subject

Essential reading

For full details, please refer to the reading list.

Dixit, Avinash K. Optimization in Economics Theory. (Oxford University Press) Sydsæter, Knut, Peter Hammond, Atle Seierstad and Arne Strom Further Mathematics for Economic Analysis. (Pearson Prentice Hall)

Students should consult the appropriate *EMFSS Programme Regulations*, which are reviewed on an annual basis. The *Regulations* provide information on the availability of a course, where it can be placed on your programme's structure, and details of co-requisites and prerequisites.

Syllabus

This is a description of the material to be examined. On registration, students will receive a detailed subject guide which provides a framework for covering the topics in the syllabus and directions to the essential reading

Techniques of constrained optimisation.

This is a rigorous treatment of the mathematical techniques used for solving constrained optimisation problems, which are basic tools of economic modelling. Topics include: Definitions of a feasible set and of a solution, sufficient conditions for the existence of a solution, maximum value function, shadow prices, Lagrangian and Kuhn Tucker necessity and sufficiency theorems with applications in economics, for example General Equilibrium theory, Arrow-Debreu securities and arbitrage.

Intertemporal optimisation. Bellman approach. Euler equations. Stationary infinite horizon problems. Continuous time dynamic optimisation (optimal control). Applications, such as habit formation, Ramsey-Kass-Coopmans model, Tobin's q, capital taxation in an open economy, are considered.

Tools for optimal control: ordinary differential equations. These are studied in detail and include linear 2nd order equations, phase portraits, solving linear systems, steady states and their stability.
